

# Week 1 Exercises

Daniel Jackson

July 6, 2022

Please complete all exercises below WITHOUT using any libraries/packages.

## Exercise 1

Assign 10 to the variable x. Assign 5 to the variable y. Assign 20 to the variable z.

```
#your code below  
x<-10  
y<-5  
z<-20
```

## Exercise 2

Show that x is less than z but greater than y.

**Note:** your output must be a SINGLE boolean, do not output a boolean for each expression.

```
#your code below  
x<z & x>y
```

```
## [1] TRUE
```

## Exercise 3

Show that x and y do not equal z.

**Note:** your output must be a SINGLE boolean, do not output a boolean for each expression.

```
#your code here  
x != z & y != z
```

```
## [1] TRUE
```

## Exercise 4

Show that the formula  $x + 2y = z$ .

**Note:** your output must be a **SINGLE** boolean

```
#your code below  
x + 2*y == z
```

```
## [1] TRUE
```

## Exercise 5

I have created a vector (test\_vector) of integers for you. Determine if any of x, y, or z are in the vector.

**Note:** your output must be a **SINGLE** boolean, do not output a boolean for each expression.

```
test_vector <- c(1,5,11:22)  
#your code below  
x%in%test_vector|y%in%test_vector|z%in%test_vector
```

```
## [1] TRUE
```

## Exercise 6

Show which value is contained in the test vector. To do this you will need to create an element-wise logical vector using operators.  $x == \text{vector}$ . Once you have done that you will need to use slicing to return all indices that have matches. **Note:** your output should be two integers

```
#your code below  
test_vector[(x == test_vector)|(y == test_vector)|(z == test_vector)]
```

```
## [1] 5 20
```
